Math-3 VOCABULARY 2-6 (Polynomials)

<u>Polynomial</u>: An equation (or an expression) with same-base powers being added that are raised to a <u>natural</u> <u>number exponent</u>.

Example: $y = 8x^5 + 5x^4 + 9x^3 + x^2 + 2x + 3$

Not a polynomial $y = x^{0.5} + 3x^{2/3} + 6\sqrt{x}$

Degree: the largest exponent of the polynomial.

$$y = -8x^5 + 5x^4 + 9x^3 + x^2 + 2x + 3$$

Lead coefficient: the coefficient of the largest power.

<u>Standard Form Polynomial</u> A polynomial ordered so that the exponents get smaller from the left-most term to the right-most term. $y = 8x^5 + 5x^4 + 9x^3 + x^2 + 2x + 3$

<u>Term</u>: powers (or the constant) separated by either a '+' or '-' symbol.

Number of terms: If all terms are present, a 2nd degree polynomial as 3 terms in standard form.

$$y = 2x^2 - 4x + 5$$

If you include the number <u>zero</u> as a possible coefficient, an "n-th degree polynomial has n+1 terms (i.e., a 3rd degree has 4 terms). $y = 4x^3 + 0x^2 - 4x + 5$

Intercept Form Polynomial A polynomial that has been factored into *linear factors*, from which you can identify the input values that make the output value equal to zero.

Example: y = 6(x+4)(x+3)(x-2i)(x+2i)

Linear factors: the exponent of the power is a '1'.

Why do we call these linear factors?

y = mx + b

The linear equation is a 1^{st} degree polynomial so (x + 2) is a linear factor

<u>Solve by factoring</u>: If the equation has only one variable ('y' has already been set to zero), solve by factoring means to convert a standard form polynomial into intercept form (by factoring) and then identifying the zeroes of the polynomial. $y = 6x^4 + 42x^3 + 96x^2 + 28x + 48$

$$0 = 6(x+4)(x+3)(x-2i)(x+2i)$$

x = -4 x = -3 x = 2i x = -2i

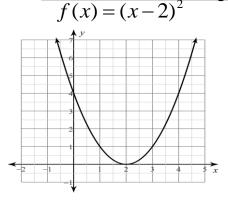

<u>Find the zeroes</u>: means that the equation has two variables. 1^{st} step: set y = 0, then solve by factoring.

If the polynomial is already in intercept form: "solve by factoring " means just find the zeroes.

$$D = (x+5)(x-2)(x-\sqrt{3})(x+\sqrt{3})$$

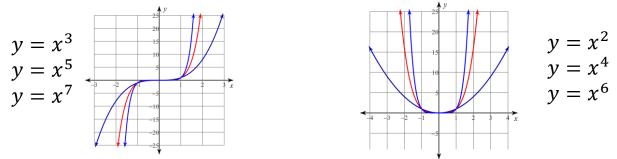

$$x = -5 \qquad x = 2 \qquad x = \sqrt{3} \qquad x = -\sqrt{3}$$

The "<u>end behavior</u>" of a function means: <u>"on the right end of the graph</u> is the <u>y-value going UP or DOWN</u>? <u>And "on the left end of the graph</u>, is the <u>y-value going UP or DOWN</u>?

In English we could say: "up on right, up on left"

As 'x' gets bigger (right end) 'y' gets bigger (goes upward) As 'x' gets smaller (left end), 'y' gets bigger (goes upward) The "<u>end behavior</u>" of all <u>odd-degree polynomials</u> is the same. The graphs of all <u>even-degree polynomials</u> is the same. The graphs below are:

Reflection across the x-axis will change the end-behavior.
